

14-Extreme Value Estimation with Package FAmle

2024-10-21

1 Introduction

Here, it is described how to fit distributions to a given hydrological data set. Our intention here is to provide an example how easy and powerful distribution fitting can be done in R. More information can be found in Rice(2003), Hogg(2004), Coles (2001) and in the help file of package FAmle (Aucoin, 2001). For the given example, a data set from the US Geological Survey (USGS, <http://waterdata.usgs.gov/nwis>) will be employed. The dataset consists of annual maximum daily **peakflows** (ft³/s) that were observed at a hydrometric station located at River James (Columbia). First the packages and the data set is loaded, then it is tested for potential trends and autocorrelation

```
## load required packages
library("FAmle")
library("FAdist")
library("MASS")
library("zoo")
library("readr")
library("dplyr")
library("lubridate")
```

```
## St James River, Columbia
jamesriver <- read_csv("jamesriver.csv", col_types = c("D", "n"))

flow <- jamesriver$flow

par(mfrow=c(1, 2))
plot(jamesriver$date, jamesriver$flow, type="b", cex=0.4, pch=19, cex.axis=0.75, xlab="Year",
     main="James River")
lines(lowess(jamesriver), col="red")
acf(jamesriver$flow, main="")
```

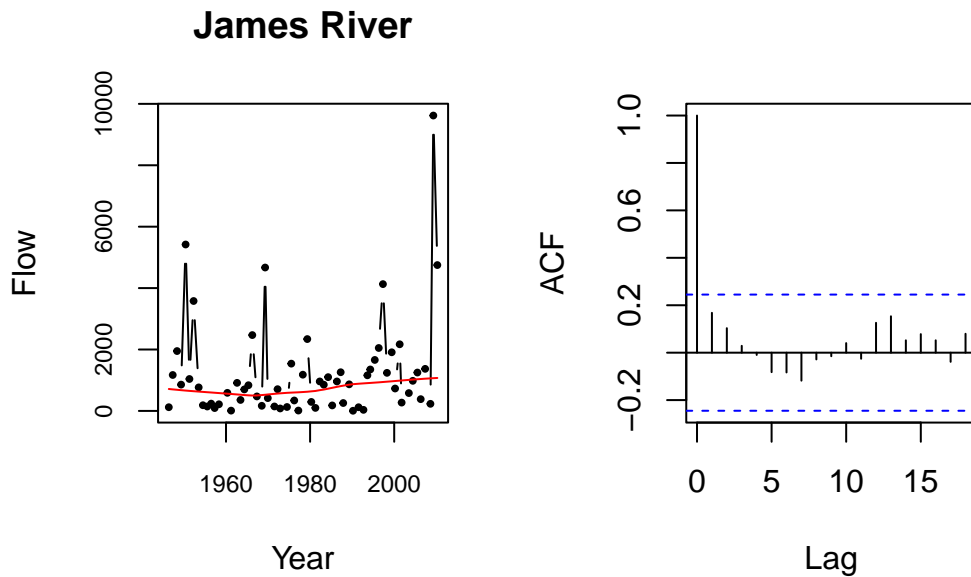

Figure 1: Time series (left) and auto-correlation plot (right) the daily flow (in ft³/s data set). The red smoothed line corresponds to a lowess fit.

2 Empirical Quantiles

```
hist(flow, probability=TRUE, xlab="flow (ft^3/s)")
rug(flow)
lines(density(flow))
```

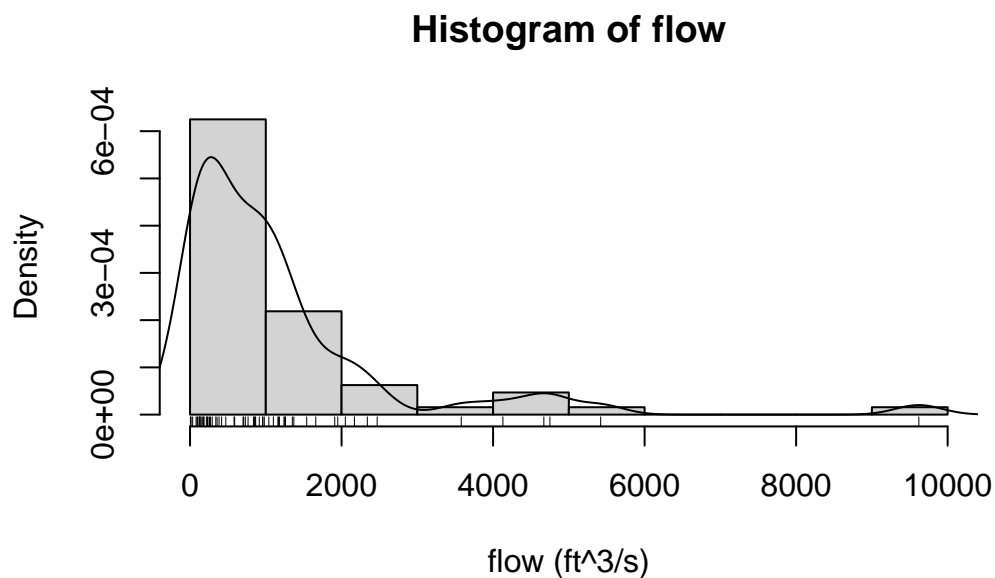

Figure 2: Histogram and empirical density of peak discharge.

If the data series is long enough, one may be tempted to use empirical quantiles, i.e. model and parameter free extrapolation from the data. We use this value as a baseline for the comparison with the model derived quantiles:

```
quantile(p=c(0.95, 0.99), flow)
```

```
95% 99%  
4589 6974
```

3 Lognormal Distribution with 2 Parameters

The Lognormal distribution is often regarded as a plausible model for this type of data. However, other distributions such as Weibull, Lognormal with three parameters, and Johnson distributions may provide better fitting results. We will try some of them. The parameters of the distribution are estimated using maximum likelihood by the mle function contained in package “FAMle”, except for the Johnson distribution which needs a different procedure. Parameters of the fitting can be obtained as follows. It is important to pay attention to goodness-of-fit parameters (log likelihood and AIC) which provide us information about how good the model explains the corresponding data set.

```
fitLn2 <- mle(x=flow, dist="lnorm", start=c(0.1, 0.1))  
fitLn2
```

```
-----  
Maximum Likelihood Estimates  
-----  
Data object:  flow  
Distribution:  lnorm  
  
----- Parameter estimates -----  
  
          meanlog.hat sdlog.hat  
Estimate      6.294      1.4878  
Std.err       0.186      0.1319  
  
----- Goodness-of-Fit -----  
  
log.like      aic      ad      rho  
-518.8617 1041.7234    0.9627 0.9884  
-----
```

```
## automatic diagnostic plots  
plot(x=fitLn2, ci=TRUE, alpha=0.05)  
  
## which probability has a flow >= 3000  
## --> two functions to provide the same result:  
  
### standard R function  
plnorm(3000, meanlog=fitLn2$par.hat[1], sdlog=fitLn2$par.hat[2])
```

```
[1] 0.8751862
```

```
### function from the FAMle package
distr(x=3000, dist="lnorm", param=c(fitLn2$par.hat[1], fitLn2$par.hat[2]), type="p")
```

```
[1] 0.8751862
```

```
## same for quantile (flow >= 95% quantile)
qlnorm(p=0.95, meanlog=fitLn2$par.hat[1], sdlog=fitLn2$par.hat[2])
```

```
[1] 6252.526
```

```
distr(x=0.95, dist="lnorm", param=c(fitLn2$par.hat[1], fitLn2$par.hat[2]), type="q")
```

```
[1] 6252.526
```

```
## empirical quantile
quantile(p=0.95, flow)
```

```
95%
4589
```

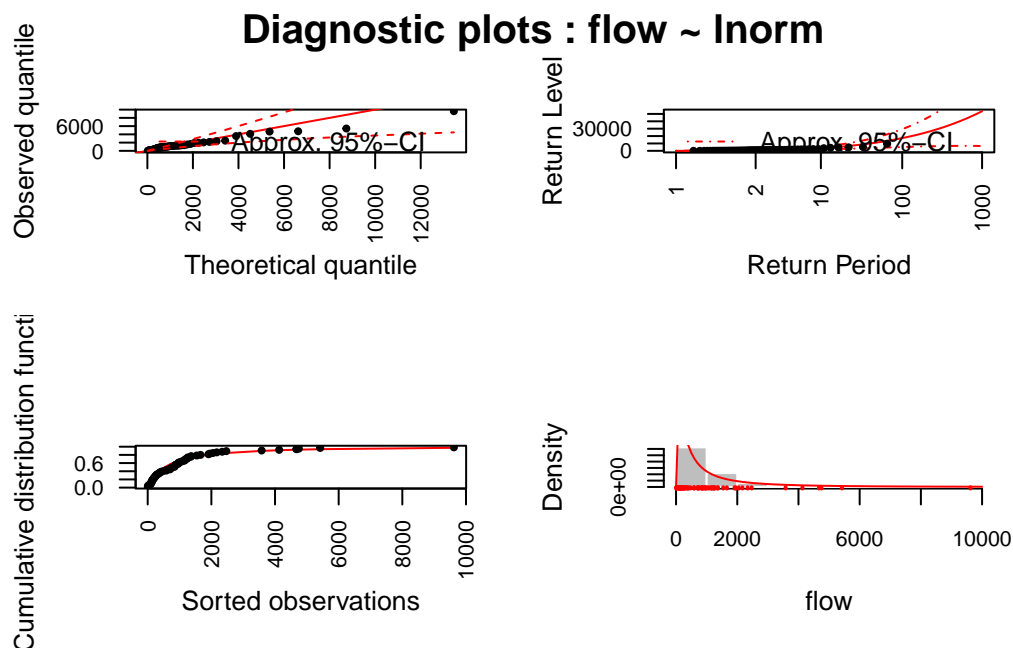

Figure 3: Plot of the mle object corresponding to the fitting James River data using a Log-normal distribution

The function `mle()` provides also some goodness-of-fit statistics. This function creates a special kind of object which can be used inside of the standard R functions, e.g., `plot()`. A function called `plot.mle` may be used to generate a series of four diagnosis plots (Figure 3) for the mle object. Diagnostic plots for the model fitted to the dataset. The dashed red lines correspond to the lower and upper confidence bounds (defined by alpha) of the approximated 95% confidence intervals derived using the observed Fisher's information matrix in conjunction with the so-called delta method.

Once the function is fitted to a distribution, these parameters can be used to calculate different quantiles. In this way we can find, for example, the value of the flow which has a probability lower than 5% or which is the probability of a flooding event of a certain flow.

Now repeat for the 99% quantile

...

And extreme floods: 1% quantile

...

The probability of a peakflow of 3000 ft³/s is obtained by either function “plnorm” or “distr” like follows:

```
plnorm(3000, meanlog=fitLn2$par.hat[1], sdlog=fitLn2$par.hat[2], lower.tail=TRUE)
```

```
[1] 0.8751862
```

```
distr(x=3000, dist="lnorm", param=fitLn2$par.hat, type="p")
```

```
[1] 0.8751862
```

4 Lognormal Distribution with 3 Parameters

Let's repeat the procedure for a Lognormal distribution with three parameters. In this case the package FAdist is required. Results are presented in ?@fig-mle-ln3

```
## Fit a lognormal distribution with three parameters
fitLn3 <- mle(x=flow, dist="lnorm3", start=c(0.5, 0.5, 0.5))
fitLn3
```

```
-----
                Maximum Likelihood Estimates

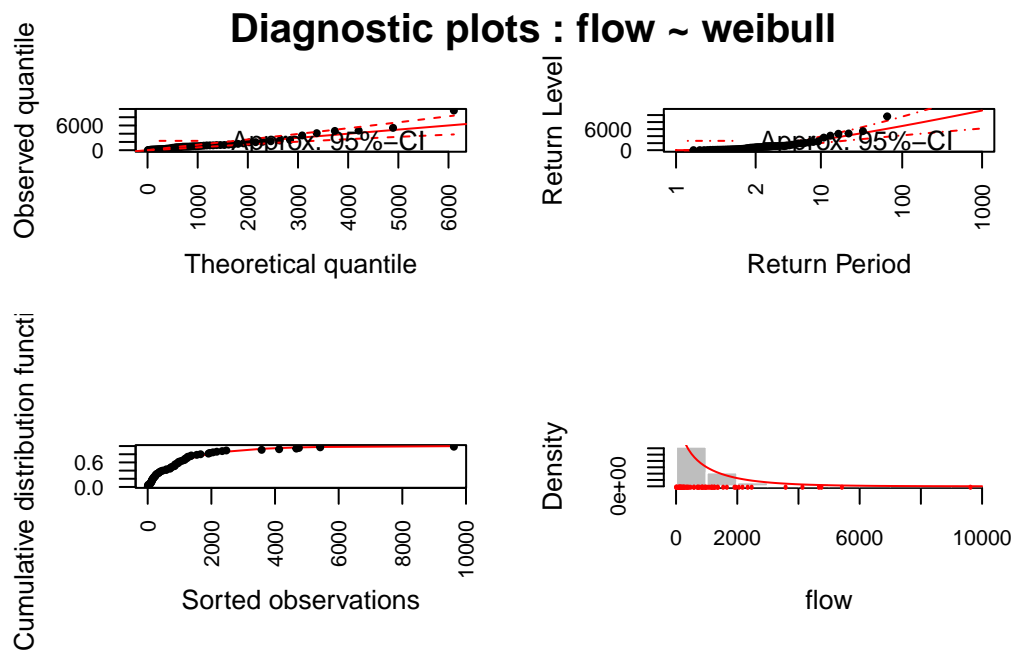

Figure 7: Plot of the mle object corresponding to the fitting James River data using a LN3 distribution

5 Exercise: Extreme values of the Elbe river

Now load the Elbe River data from the beginning of the course and note that we need annual maximum values.

```
elbe <- read_csv("https://raw.githubusercontent.com/tpetzoldt/datasets/main/data/elbe.csv",

## annual maximum discharge
elbe_annual <-
  mutate(elbe, year = year(date)) |>
  group_by(year) |>
  summarize(discharge = max(discharge))

plot(discharge ~ year, data = elbe_annual)

## check for trend and autocorrelation between years
MannKendall(elbe_annual$discharge)
acf(elbe_annual$discharge)

fitLn3 <- mle(x=elbe_annual$discharge, dist="lnorm3", start=c(1, 5, 100))
fitLn3

flow <- elbe_annual$discharge

hist(flow, probability=TRUE, breaks = 10)

rug(flow)
```

```
lines(density(flow))

xnew <- seq(min(flow), max(flow), length = 100)
funLn3 <- function(flow) distr(x=flow, model=fitLn3, type="d")
lines(xnew, funLn3(xnew), col="red")
```

Important: The method described so far assumes stationarity of conditions, i.e. absence of meteorological and hydrological trends. Discuss, how climate warming already influences validity of the described method, and which methods need to be applied instead.
